

What is the difference between the repository pattern and the client–server pattern ?

*The repository pattern consists of two main components:*

- *A central data store*
- *A collection of components that operate on it to store, retrieve, and update information.*

*and the decision of how those components will interact is kind of complicated .*

*The client-server pattern consists of two main components:*

- *Server components offer services*
- *Clients access them using a request/reply protocol.*

*and the client may send to the server an executable function (call back).*
